Contents

Preface

This guide is intended for qualified technicians who will deploy a Polycom KIRK Wireless Server Solution. To qualify to deploy a Polycom KIRK Wireless Server Solution, you must have completed the technical training successfully. This guide covers both 1G8 and 1G9 deployment.

Scope

The Deployment Guide provides instructions and best practices for deployment of the following solutions:

- Polycom KIRK Wireless Server 500
- Polycom KIRK Wireless Server 1500
- Polycom KIRK Wireless Server 8000
- Polycom KIRK Wireless Server 6000 and 300
- Polycom KIRK Wireless Server 600v3

The purpose of this guide is to familiarize you with the procedures that are needed to carry out a site survey.

Note Specific deployment of the Polycom KIRK Wireless Server 600v3 multi-cell is not covered by this guide. Refer to the training material from the Polycom KIRK Wireless Server 600v3 training course and the Polycom KIRK Wireless Server 600v3 Installation and Configuration Guide for more information.

At the completion of this guide you should be comfortable with the following:

- Using the deployment handset to measure and record Q - and RSSI values (RF values).
- Selecting a proper mounting location for base stations and repeaters
- Operating and configuring the deployment base station
- Operating the deployment handset
- Documenting the deployment

Before You Begin

This guide assumes the following:

- You have a working knowledge of deployment in general.
- You have completed the technical training.

Related Documentation

For information about Polycom KIRK Wireless Server Solutions not covered by this manual, refer to the following documentation.

Table -1 *Additional Documentation*

Subject	Documentation
Polycom KIRK Handsets	User Guides on www.polycom.com
Polycom KIRK Wireless Servers	User Guides www.polycom.com
Polycom KIRK Technical News	Newsletter that describes software changes, bug fixes, outstanding issues, and hardware compatibility considerations for new software releases. To subscribe, send an e-mail to dectservicenewssubscribe@polycom.com

Terminology

Table -2 Terminology

Term	Definition
Deployment	The act of locating the mounting location and installing base stations and repeaters
RF	Radio Frequency
Deployment Base Station	The deployment base station is included in the Polycom KIRK Deployment Kit and propagates the DECT radio signal for deployment purposes.
Repeater	Repeaters synchronize wirelessly to a programmed host base station and repeat voice channels to create a larger coverage area
Site survey	A site survey comprises the action of locating the mounting location and noting the cabling requirements for all base stations and repeaters.
Charging cycle	The length of time necessary to recharge the handset's battery
Ni-MH	Nickel -Metal Hydride
LED	Light Emitting Diode
Speech channel	A speech channel is used to carry communication between the handset and the base station or repeater.
Q Value	Signal Quality Factor value. An expression of the bit failure rate in the communication between the handset and a base station. The value has a max. of 64, equal to no bit errors measured.
RSSI Value	Radio Signal Strength Indication value. A relative expression for the signal strength of a base station as measured by the handset at a given location.
Handover	A process initiated by the handset in which the speech channel carrying an active conversation is passed from one base station to another.

1

Deployment Hardware

This section describes the hardware components of the Polycom KIRK Deployment Kit.

The Deployment Kit is used to determine the number of base stations and repeaters required for a Polycom KIRK Wireless Server Solution. Furthermore, using the deployment kit it is possible to identify the proper mounting locations for base stations and repeaters, and to plan for the cabling of the base stations.

Site surveys should only be carried out by technicians who have passed the Polycom KIRK Training course for the multicell solutions KWS600V3, KWS6000 or KWS8000.

Figure 1-1 Deployment Kit Case

Deployment Base Station

The deployment base station is a Polycom KIRK Wireless Server 300. The deployment base station must only be used for deploying the Polycom KIRK Wireless Server Solution. It is not approved for connection to any public network

Figure 1-2 KWS300 Deployment Base Station

Base Station Power Supply

The KWS300 base station is powered by PoE, and is supplied without a PoE injector. You will have to buy the PoE injector separately.

Handsets

The Polycom KIRK Deployment Kit comes with a 4040 handset and a 1619 handset, a charger for each handset, and a power supply for each charger. Handset batteries are included with each handset.

The handsets have been subscribed to the deployment base station from the factory. and are identified as handsets #1 and handset #2. When you place a call between the handsets, you can determine the assigned handset number.

You can add and remove handsets when necessary without the need for special software. For more information about subscribing and unsubscribing handsets, refer to the handset user guides on www.polycom.com.

Deployment Handset

The 1610 handset has special software implemented and can be used as a diagnostic tool. In this guide it is referred to as a deployment handset. For more information about using the 1610 handset as a diagnostic tool, refer to the 1610 Handset User's Guide on www.polycom.com.

When a deployment handset is subscribed to the deployment base station you hear an acoustic delay of 40 milliseconds in the handset when you talk in it. That is, your voice gets back to you as an echo. This is necessary in order to use the handset as a deployment handset.

Note You can distinguish the 1610 handset from the 4040 handset by the label on the back which says "Diagnostic Handset."

Deployment Handset Power Supply

The deployment handset is supplied with a 9V/300mA adaptor. Current consumption is max. 130mA. It is connected to the plug at the bottom of the charger.

Chargers and Power Supplies

Which charger and power supply you need to use vary depending on the region. The following is a list of the different chargers and power supplies and their part number.

Table 1-2 Charger and Power Supply Part Numbers

Area	Item	Part Number
EU	Deployment Handset Power Supply	84642420
EU	Charger	84642450

Table 1-2 *Charger and Power Supply Part Numbers*

UK	Power Supply	84642421
UK	Charger	84642450
US	Power Supply	84642455
US	Charger	84642450

2

Radio Coverage Properties

The deployment of base stations and repeaters is a central aspect of any Polycom KIRK Wireless Server Solution. For the Polycom KIRK Wireless Server installation to be successful, you must follow the deployment concepts explained in this guide.

You must perform a site survey to determine the optimal location and the total number of base stations required for a given installation.

Note Radio coverage depends on building construction materials, methods of construction, and the surrounding environment. Therefore, each installation is unique when in regard to the number and location of base stations.

Radio Coverage Planning

While an extensive guide to effective RF coverage planning is outside the scope of this manual, the following points should be taken into consideration when planning the site.

- The deployment base station provides a typical coverage radius similar to that of a regular base station and propagates in all directions. The exact coverage range depends on the building architecture, wall material and surroundings.
- Wireless handsets can move between the coverage areas of different base stations and repeaters while receiving continuous service and maintaining conversations in progress.
- For efficient handover of conversations between base stations, deploy multiple base stations with sufficient overlap of coverage; that is, plan for some areas to be covered by more than one base station. Overlaps are necessary to allow a handset time to handover to a base station from which it receives a better signal quality.
- Avoid placing base stations near other electronic equipment, large machinery, metal constructions, etc., as the range can be severely affected. Base stations should be placed between 6- 12 feet/1.8-3.6 meters in height on a wall or up to 30 feet/10 meters when suspended from a ceiling. If they

are placed any lower, persons walking around could interfere with the radio signal. The coverage area can be adversely affected if the base stations is mounted improperly.

- Ensure that there is not a residential DECT system (home DECT) on the site.

Radio Coverage Overlap

Radio coverage overlap is required between adjacent cells to allow for the handover of active conversations from base station to base station or repeater.

Coverage overlap occurs when the radio fields of multiple base stations overlap each other. Base stations must be placed in such a way that the radio coverage from one base station to another overlaps by 30 to 45 feet/10-15 meters.

An overlap is required so that as the handset moves about, the various coverage zones base stations have time to hand the call off to another base station.

If the overlap area is not enough - less than 30 – 45 feet/10-15 meters there is a risk of the connection being dropped while moving from one coverage area to another. However, too much overlap results in a wasted coverage area.

In order to support the handover of calls from one base station to another, a maximum travelling speed for the handset of 3mph (5km/h) is allowed relative to the size of the overlap.

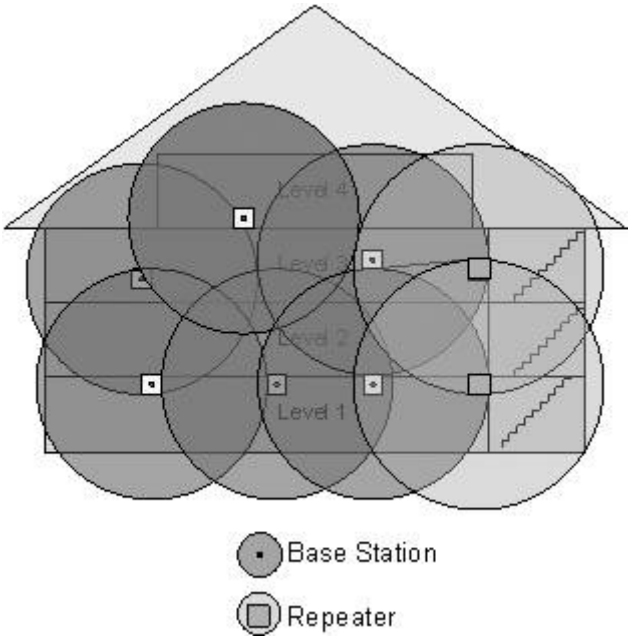
Horizontal and Vertical Overlap

Base stations are omni-directional, which means that the RF signal is propagated vertically and horizontally from the base stations and repeaters. Depending on building materials the base station coverage area will typically extend to more than one floor of a structure.

In the Figure 2-1 multi-zone building installation, the coverage areas overlap horizontally, which allows the handset to roam the structure without interruption.

The handset will not necessarily switch over to the base station from which the strongest signal is received. The handset will remain connected to a base station as long as the quality of the received signal is acceptable.

Figure 2-1 Horizontal and Vertical Overlap



High Density Traffic Coverage

The following contains information about high density traffic coverage in the following wireless servers:

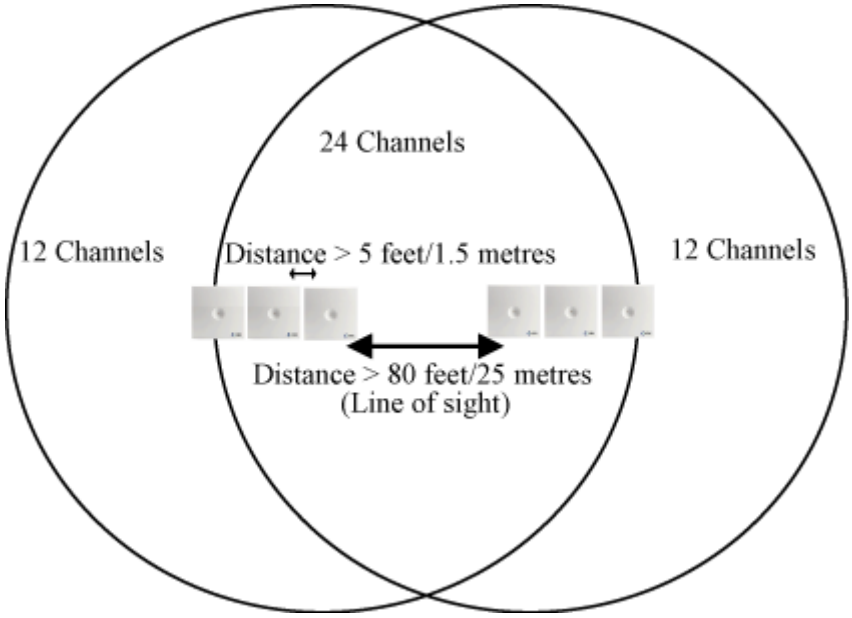
- KWS1500 - 1.8 GHz
- KWS1500 - 1.9 GHz
- KWS6000 - 1.8 GHz
- KWS6000 - 1.9 GHz
- KWS300 - 1.8 GHz
- KWS300 - 1.9 GHz
- KWS8000 - 1.8 GHz
- KWS8000 - 1.9 GHz
- KWS600v3 - 1.8 GHz
- KWS600v3 - 1.9 GHz

KWS 8000 and KWS 1500 - 1.8 GHz

Each base station supports up to four simultaneous conversations. In some applications more channels are needed in a dense area. To support these installation requirements, up to three base stations can be placed in the same general area to provide extra traffic capability.

Up to three base stations can be mounted next to each other, with a recommended minimum distance of 5 feet / 1.5 meters. If a fourth base station is required in a high traffic area, it must be placed at least 80 feet/25 meters away if a direct line of sight exists between the fourth base station and the group of three to prevent interference. Alternatively, the fourth base station must be moved away from the group of three base stations equal to a signal loss of 15 – 20 dB.

Figure 2-2 *Example: 1.8 GHz*



Note It is possible to mount 6 base stations in close proximity of each other (minimum 1,5 meters) provided that 3 of the bases are assigned even time slots and the remaining 3 base stations are assigned uneven time slots.

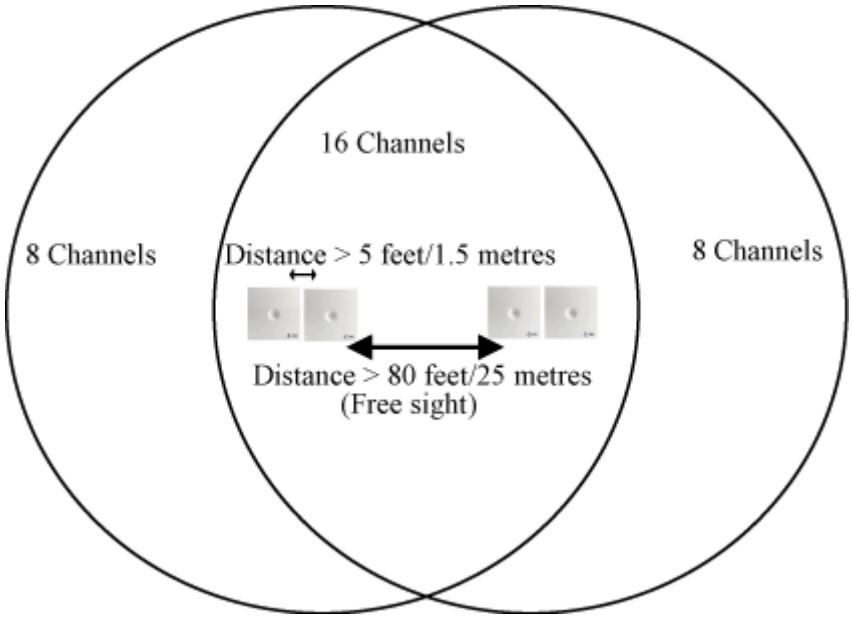
KWS 8000 and KWS1500 - 1.9 GHz

Each base station supports up to four simultaneous conversations. In some applications more channels are needed in a dense area. To support these installation requirements, up to two base stations can be placed in the same general area to provide extra traffic capability.

Up to two base stations can be mounted next to each other, with a recommended minimum distance of 5 feet / 1.5 meters. If a third base station is required in a high traffic area, it must be placed at least 80 feet/25 meters

away if a direct line of sight exists between the third base station and the group of two to prevent interference. Alternatively, the third base station must be moved away from the group of two base stations equal to a signal loss of 15 – 20 dB.

Figure 2-3 *Example: 1.9 GHz - USA*



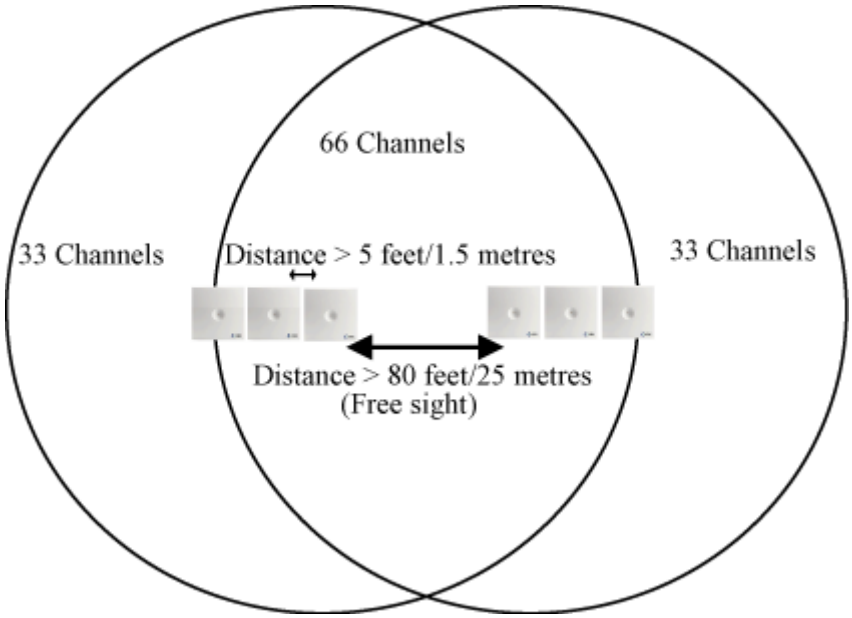
Note It is possible to mount 4 base stations in close proximity of each other (minimum 1,5 meters) provided that 2 of the bases are assigned even time slots and the remaining 2 base stations are assigned uneven time slots.

KWS600v3 - KWS 6000 1.8 GHz

Each wireless server supports up to 11 simultaneous conversations. In some applications more channels are needed in a dense area. To support these installation requirements, up to three wireless servers can be placed in the same general area to provide extra traffic capability.

Up to three wireless server can be mounted next to each other, with a recommended minimum distance of 5 feet / 1.5 meters. If a fourth wireless server is required in a high traffic area, it must be placed at least 80 feet/25 meters away if a direct line of sight exists between the fourth wireless server and the group of three to prevent interference. Alternatively, the fourth wireless server must be moved away from the group of three wireless servers equal to a signal loss of 15 – 20 dB.

Figure 2-4 Example: 1.8 GHz

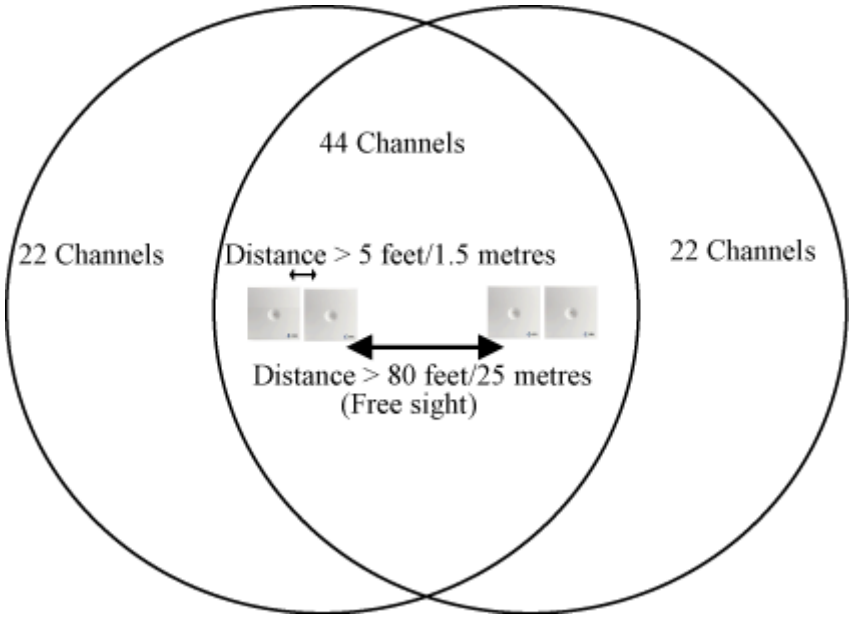


KWS600v3 - KWS 6000 1.9 GHz

Each wireless server supports up to 11 simultaneous conversations. In some applications more channels are needed in a dense area. To support these installation requirements, up to two wireless servers can be placed in the same general area to provide extra traffic capability.

Up to two wireless server can be mounted next to each other, with a recommended minimum distance of 5 feet / 1.5 meters. If a third wireless server is required in a high traffic area, it must be placed at least 80 feet/25 meters away if a direct line of sight exists between the third wireless server and the group of two to prevent interference. Alternatively the third wireless server must be moved away from the group of two wireless servers equal to a signal loss of 15 – 20 dB.

Figure 2-5 Example: 1.9 GHz



Synchronization Overlap

Note This section is relevant to the Polycom KIRK Wireless Server 6000 and the KWS 600v3.

Two types of overlap are present in a multi-cell configuration:

- The overlap created to be able to obtain synchronization between cells.
- The overlap created to establish handover when moving handset between cells.

Maximum loss (equal to distance) of signal between the cells is 25 dB.

To create handover between cells it is necessary to establish synchronization chains.

The procedure for establishing synchronization between radio units is the same way as for repeaters connected to a base station without external antenna connected. However, the following issues considered when you establish synchronization chains.

- The distance over which synchronization can take place is limited to a distance similar to a loss of max. 25dB. If the loss of signal is higher than 25dB, there is no guarantee that synchronization is stable. You can use the deployment handset to measure dB.

- We recommend that a KWS600v3 synchronizes with at least two other radio units, and that an alternative sync way is defined to ensure system redundancy. If the primary sync way is not working, the alternative sync way takes over and the synchronization chain is not broken.

Synchronization chains for the KWS600v3 Solution can be made with Primary and Secondary KWS600v3 and Polycom KIRK Repeaters.

You can only configure a Polycom KIRK Repeater to synchronize on one radio ID, and it is therefore not possible to define alternative sync ways for repeaters.

The KWS600v3 synchronizes on the DECT interface, and one KWS600v3 is configured as the Sync Master.

For more information about deploying a Polycom KIRK Wireless Server 600v3, refer to the Polycom KIRK Wireless Server 600v3 Installation and Configuration Guide on www.polycom.com.

Other Radio Coverage Effecting Factors

The following is a set of factors that may influence the voice quality of the handset.

Moving Speed

The time it takes a person to cross the common coverage area must be at least 10 seconds, because the handset needs time to scan for an alternative base station.

The Surrounding Environment

Different weather conditions can influence radio coverage. For example, a wet roof or wall can act as a shield. Also, new leaves on trees in the spring might affect the radio coverage of base stations and repeaters.

Metal Constructions

If the construction materials of the building contain metal, signal reflection may occur. When signal reflections occur, the signal may be affected even when the handset is very close to the base station. You should document these areas with the help of the customer.

Reflections can often be identified as unstable Q value in positions where the RSSI value is high. If the Q value is stable as long as the handsets is placed in a fixed position (not moving), but fluctuates significantly when moved it is probably caused by reflections from the surroundings.

If you are aware of metal in the building construction, you have to carry out a very thorough site survey.

In these situations, we recommend that you use a Polycom KIRK Wireless Server, and a minimum of four base stations to obtain proper knowledge of the radio signal propagation.

Signal Performance Measurement

Q Value

The Signal Quality Factor value (Q value) is an expression for the bit failure rate in the communication between the base stations and the handset. The highest possible Q value is 64. At this value there is no bit failures measured and excellent speech quality should be provided. The Q value is only valid in off hook mode - not in idle mode.

As the wireless handset roams the coverage area the Q value changes. When the wireless handset registers a Q value of 52 - equal to 12 bit failures measured -, the wireless handset requests a handover to an alternative base station or repeater, or eventually to another channel frequency or timeslot.

The information in the Signal Meter Display is only updated once per second, which means that the number of bit failure can be lower or higher than indicated in the display. It is therefore important to accept, that as soon as significant fluctuation of the Q value occurs, the end of the radio coverage has been reached.

RSSI

The Radio Signal Strength Indicator value (RSSI value) is a relative expression for the field strength of the signal from the base station. The RSSI value is used for selecting the alternative base station(s).

The handset chooses the base station from which the strongest RSSI signal is received as the first alternative base station. Alternative base stations are listed according to RSSI values. When the “Best alternative base station” disappears, it is replaced by the next base station with the highest RSSI value.

Q Value and RSSI Value as They Relate to Voice Quality

There is always a relationship between the coverage of the base station and the quality of sound on the handset. Sound quality is therefore, typically, directly proportionate to the distance from the handset to the radio signal source. The amount and density of any obstacles such as walls, plants, people, etc., also impact the quality of service.

Q Value

Because it is difficult to identify quality of signal by distance from the base station alone, the Q value is used as an indicator for the quality of the signal. The RSSI signal is used as an indicator for the signal strength.

The user will have an excellent quality of signal as long as the Q value is high (>52) and does not fluctuate significantly.

When there is no interference from other base stations, other equipment, or reflections from the surroundings, the relation between the Q value and the RSSI signal is as follows:

- High RSSI – high and stable Q value
- Low RSSI – low and/or unstable Q value

Note In some situations, a high RSSI value does not necessarily mean a high and stable Q value. This may occur in buildings with metal in the construction material.

Clicks, distortion, and audio breaking up is to be seen as a result of bit failures in the communication between the handset and the base station.

RSSI Signal Quality

The quality of the RSSI signal falls within three groups.

Very Good

As a guideline, an RSSI signal where the loss of signal is not higher than 10 dB relative to the signal measured near to the base station is a very good signal where only some minor clicks will be heard.

Acceptable

A RSSI signal where the loss of signal is equal to a loss of 20 dB is an acceptable signal where some clicking and popping may occur.

Not acceptable

A RSSI signal where the loss of signal is higher than 30 dB relative to 100% near to the base station is not considered as acceptable signal strength.

Identifying Repeater Locations

When you identify mounting locations for repeaters, the signal quality must be equal to a signal where it is possible to obtain a good connection between a handset and a base station.

The RSSI signal is normally not accepted when it is equal to or higher than a loss of 25 dB relative to the signal measured near to the base station.

A loss equal to 25 dB can be used as a guideline only. At the position where the repeater is mounted, the signal quality most be acceptable in terms of Q value.

- At the repeater location, place a handset that is locked to the base station to which the repeater is connected. Press the off-hook key to view the Q value.

Q value must be high and stable. If the Q value is not high and stable, the link between the base station and repeater is generating bit failures.

If this happens the bit failures measured in the link between the base station and the repeater are transferred to the connection between the repeater and the handset, which results in poor sound quality.

Signal Strength and Distance from Signal Source

The RSSI value reported by the handset is a relative expression of the signal strength, and cannot on its own be used as an indicator for the quality of the signal. The Q value must also be taken into consideration.

Example

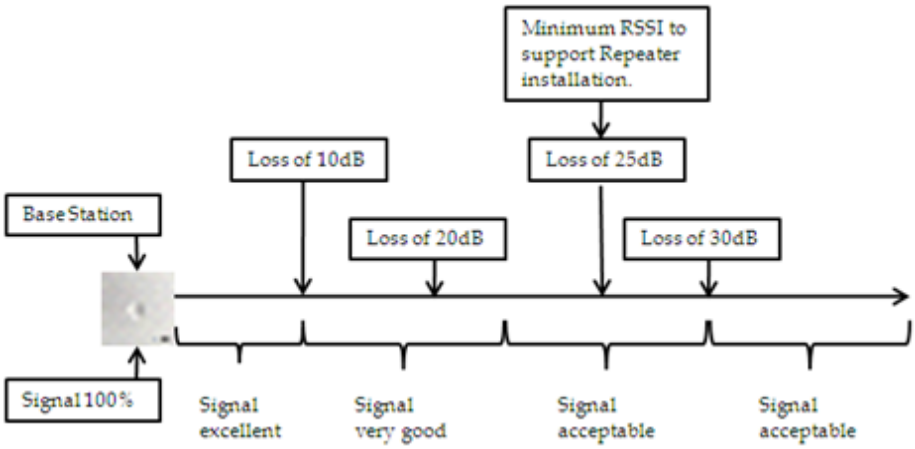
When the handset is placed right next to the base station, the signal is 100%. However, the RSSI value in the display may display only 95%.

When you move away from the base station, the RSSI value drops to 85% and you will experience a loss of 10 dB. If you move even further away, the RSSI value changes to 75% and the total loss is 20 dB.

Guideline

The values presented in Figure 2-6 are only to be used as guidelines in a situation where there are no reflections from the surroundings, and where there is no interference from other equipment.

Figure 2-6 Relation between Signal Strength and Distance from Signal Source



Repeater numbering

Base stations and repeaters both transmit a radio part number - an 8 bit number between 0-255.

The handset compares the RPN of the base/repeater to which it is currently connected to that of the RPN of the base station/repeater it wants to handover to.

The type of handover to use depends on the units involved in the handover.

.Handovers

- Handovers between two base stations must take place as connection handovers.

- Handovers between a repeater and the base station with which the repeater is synchronized should preferably take place as a bearer handovers, as this is the fastest process.
- Handovers between a repeater and a base station with which the repeater is not synchronized must take place as connection handovers.

Handover Capabilities

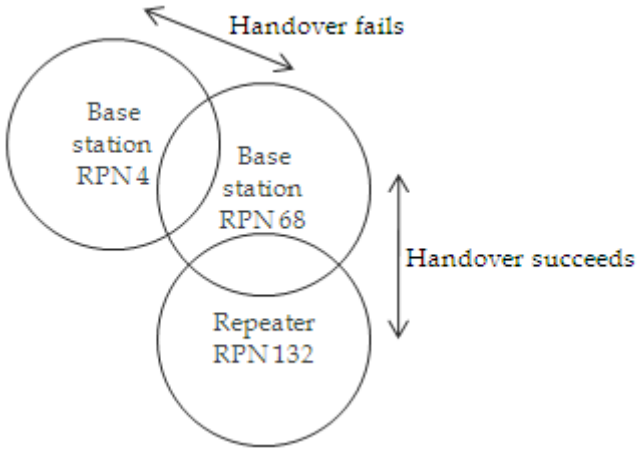
A handset cannot tell the difference between a base station and a repeater. Therefore, the RPN transmission pattern by default determines how the handover takes place. Assigning the recommended repeater RPN is therefore very important.

Polycom Kirk base stations transmit a pattern that determines whether to use a connection or a bearer handover.

By default the base stations are configured to perform a bearer handover if there is a difference of 64, 128 or 192 between the two RPNs.

In systems with more than 64 base stations you must be careful when you reuse RPNs. That is, base stations that are mounted in close proximity of each other can not have a difference in RPN of 64, 128, or 192. The handset will not be able to make a connection handover as shown in Figure 2-7.

Figure 2-7 RPN and handovers



Also, a handset must never be able to detect two radio units (base stations or repeaters) with the same RPN at the same time. The handset will not be able to make a handover. If an RPN is reused, the units must be placed at a fair distance from each other.

Numbering pattern

The following table, Figure 2-1, lists the recommended numbering of repeaters in systems with up to 255 base stations.

.

Table 2-1 Base station and repeater numbering pattern

Base station	Repeater 1	Repeater 2	Repeater 3

Deployment Procedure

Begin the site survey by interviewing the customer representative familiar with the full expectation of coverage and performance of the Polycom KIRK Wireless Server Solution. During this conversation, collect the following documents and information:

- View site blueprints / maps
- Identify any special conditions such as large metal surfaces, heavy machinery etc., that may affect the signals and mark this on the blueprints.
- Identify WLAN infrastructure
- Verify with the customer where coverage is required
- Determine the number of handsets to be deployed and possible growth
- Determine traffic expectations
- Discuss restricted areas where radio coverage is not required
- Locate the expected installation point of the Polycom KIRK Wireless Server and document any additional hardware that may be necessary for the site.

Note Always, properly judge special requirements for each site.

Preparing the Hardware

Before beginning the physical site survey process, execute the following steps:

- Charge the batteries for the deployment handsets and deployment base station.
- Turn on the deployment base station and verify the power LED is lit.
- Turn on the deployment handsets and verify the handsets are subscribed to the deployment base station.

- Establish a test call between handsets and verify sound quality.

Note The handsets are subscribed to the base station from the factory. If the handsets are unsubscribed, refer to the handset user guides on www.polycom.com for more information on how to subscribe a handset.

Documenting Radio Requirements and Results

The following information must be documented:

- If an agreement is made with the customer to accept areas where radio coverage is less then acceptable, this should be documented and agreed upon with the customer.
- Note the results of the site survey on the relevant floor plan documents.
- Clearly document the location of the deployment base station and the expected mounting location of the permanent base station or repeater and the coverage area provided from this location.
- For multi-floor deployments, make sure to note the floor where the deployment base station is located.
- Include wiring considerations and special installation instructions in the documentation.

Deployment Steps

This section contains information about:

- "Deployment of a Single Floor Building" on page 31
- "Deployment of a Wider Single Floor Building" on page 32
- "Deployment of a Multi Floor Area" on page 33

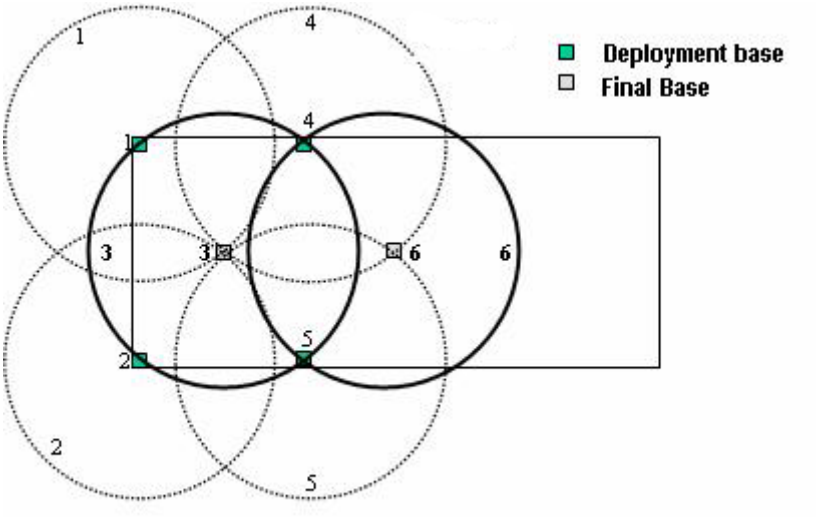
Note When you perform a site survey, always ensure that all doors, including fire doors, are closed.

Deployment of a Single Floor Building

- Determine the outer points of the building for placing the deployment base station. (points 1, 2 on figure A/Figure 3-1).
- Place the deployment base station near point 1 at a height of 6-8feet/1,8-2,50 meters and begin the measurement of the radio signal. Proceed at approximately a 45 degree angle away from the deployment base station. Mark on the map the boundary of the radio coverage cell.
- Move the deployment base station to point 2 at a height of 6-8 feet/1,8-2,5 meters and in the same technique measure the signal. Mark on the map the boundary of the radio coverage.

- Continue to measure and document the radio signal from each of the main points on the map. A center crossing point will indicate the possible best location for mounting the permanent base station.
- Once identified, place the deployment base station in the center of the area at the point where each of the coverage cells crossed during deployment. Verify the coverage of the cell reaches all areas expected.

Figure 3-1 *Determining Outer Points of the Building*



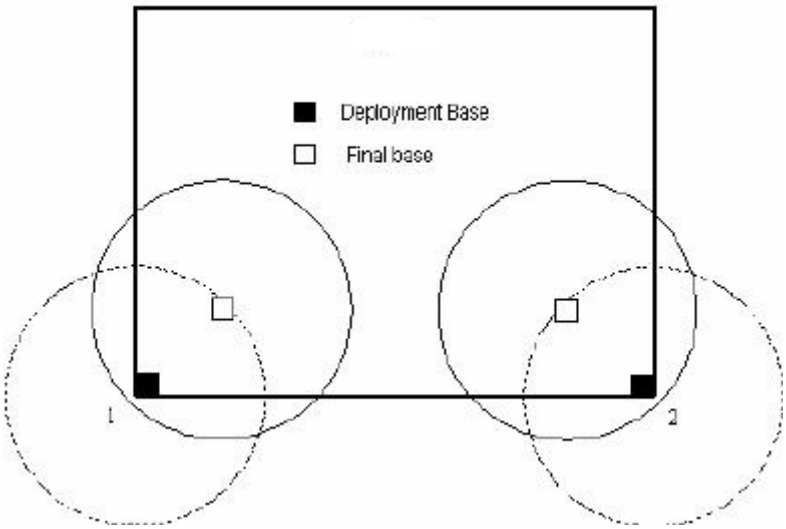
Note Figure 3-1 does not consider building elements that may influence the signal strength.

Deployment of a Wider Single Floor Building

In some deployments it will be found that the placement of the deployment base station will not overlap with the deployment base station as indicated on the map below. To deploy in these environments:

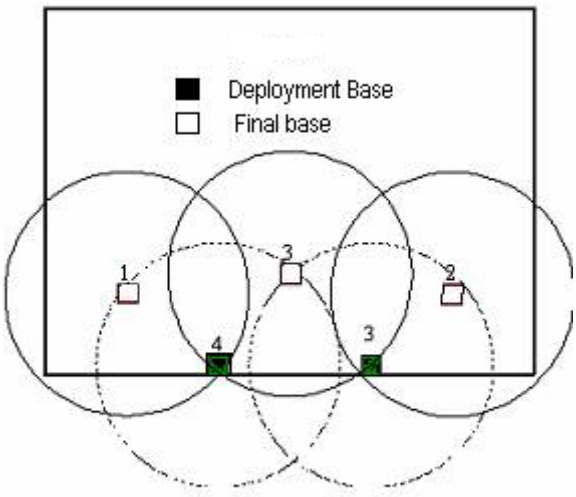
- Mark the corners of the area to be deployed. (Position 1 and 2 on figure B/Figure 3-2).
- Place the deployment base station in position 1 at a height of 6 to 8 feet/1,8-2,5 meters.
- Measure the signal in a 45 degree angle towards the center of the area. Document the boundary of the signal.
- Proceed to point 2 and perform the same test. Document the boundary of the signal.
- Placing the deployment base station on the 2 boundary points will provide a good testing location for permanent base station 1 and 2. Place the deployment base station in these locations; measure and document the boundaries of the coverage cell.

Figure 3-2 Deployment Points 1 and 2



- Mark where the boundaries of the permanent base station 1 and 2 intersect with the wall being used as the base point.
- Use these two locations (deployment points 3 and 4) as the points for placing the deployment base station to determine the location of permanent base station 3.

Figure 3-3 Deployment Points 3 and 4



Deployment of a Multi Floor Area

There are two approaches in surveying a multiple story building:

- Survey each floor as individual parts.When surveying each floor as individual parts, the excess radio signal propagated between floors is considered used for high density traffic. This approach uses more base stations and provides better conditions for sound quality and simultaneous conversations.
- Place the deployment base station on one floor and continue the measurement of coverage on adjacent floors. When measuring signal across adjacent floors, placement of permanent base stations may be adjusted. This approach uses fewer more specific base station locations in sites where high density traffic is not typically necessary.

Recommended Placement of Base Stations and Repeaters

Base stations (wall mounted) and repeaters must be placed in the right position – hanging on the wall – NEVER on the ceiling.

- Keep the base station away from steel constructions - at least 4 feet/1.20 meters
- Do not place base stations directly on metallic surfaces - at least 4 feet/1.20 meters
- Do not hide base stations behind furniture etc.
- Do not paint the base station as paint is containing metallic/carbon particles
- The base station must be placed where the signal is needed

4

Kit Configuration

This section provides information about how to install the kws300, and how to subscribe handsets to the kws300. Note that the KWS is powered by Power over Ethernet (PoE).

Installation Flow

The following lists the main steps in installing the kws300.

1. Connect the Power Injector to KWS300
2. Go to the KWS300 administration web page
3. Enter the IP deployment settings for the KWS300
4. Subscribe the DECT handsets.

KWS300 Overview

Status indicating LED on the front.

Figure 4-1 KWS300 Front view

LED Indicator Description

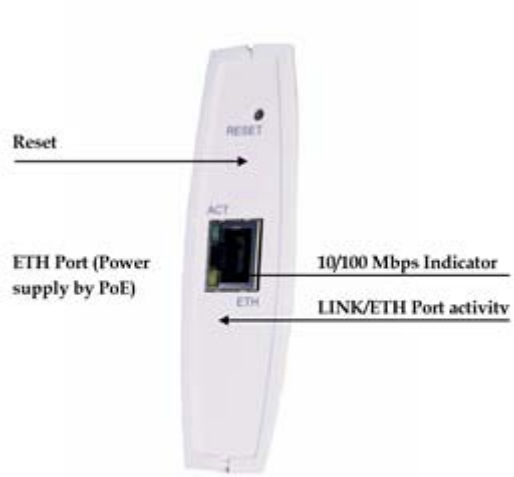
The LED indicator provides you with information about the status of the KWS300.

Table 4-1 LED Indicator

LED Indicator	Status
Steady green	OK and idle
Slow green flashing	OK and active voice call
Fast red flashing	Error
Steady red	Reset/shutdown in progress
Steady red for 5 seconds followed by red flashing	Reset to factory setting

KWS300 Faceplate

Figure 4-2 KWS 300 Faceplate



LED Functionality

Table 4-2 LED functionality

LED	Meaning
LINK Indicator	Steady: Link layer software has established connection
Flashing: Activity	
ETH Port 10/100 Mbps	10 Mbps or 100 Mbps operation

Reset Button

You can restart or reset the KWS300 by pressing the reset button on the faceplate of the KWS300.

Table 4-3 Reset Button Description

Press button	Action
Short press (2 – 5 sec)	System restarts when button is released.
Long press (5 to 9 sec.) – until front LED flashes red, then release button	Resets the system to factory default settings (original IP settings and empty user database) and restarts the system. The firmware version is not affected.

Note that when you long press, make sure to release the button right after the LED starts to flash. If you continue pressing the button, KWS300 will probably not reset to default factory settings.

Pre-installation Steps

The following are steps that need to be completed before you can begin the actual installation.

Power

To power up, connect KWS300 to a PoE LAN Ethernet net, or use a power injector (not included on delivery).

Default Logon information

To enter the web based Administration Page you need the following information.

Table 4-4 System Access Information

Initial System Access KWS300	
Static IP Address	192.168.0.1
Network Mask	255.255.255.0
User Name	admin
Password	kws300

System Information

To set up and configure the solution, you need the following information.

- The ARI code, which is the same as the serial number for the KWS300. See label on the rear of the KWS300 unit (ARI code is the SN number Item.)
- AC codes (optional). The AC code is a customer-defined optional subscription pin code of a maximum of eight digits for the individual handset. The AC can be used when connecting the handset to the KWS300.
- The handset IPEI code, which is a unique code that identifies the handset. You can see the IPEI code on the handset label (the SN number), in the handset menu, or obtain it automatically from the KWS300 when the "autocreate users" box is checked.

Activation

The following section describes the steps involved in configuring the KWS300 in deployment mode.

Enter Administration Page

You access the web based Administration Page through a standard web browser. To access the web page, you need the following information.

Table 4-5 Administration Page Access Information

Initial System Access KWS300	
Static IP Address	192.168.0.1

Table 4-5 Administration Page Access Information

Initial System Access KWS300	
Network Mask	255.255.255.0
User Name	admin
Password	kws300

To Access the Administration Page

1. Open a web browser.
2. In the Address bar, type http://192.168.0.1, and then press **Enter**.
3. Type the User Name (admin) and Password (kws300) in the dialog and then click the **OK** button. The KWS300 Administration Page appears.

Figure 4-3 Main page of the KWS300 Administration Page

IP Setup (optional)

The IP setup is only required if you connect KWS300 to a LAN network where you cannot use the default 192.168.0.1 IP address

To set up IP

1. For the IP settings, click **Configuration**, and then click the **General** tab.

Figure 4-4 General Configuration Page

2 Enter the IP settings in the corresponding fields. Please contact your IT-administrator if you do not have this information.

Configuring SIP Settings

To Configure SIP Settings

1 To configure the KWS300 SIP settings, click **Configuration**, click **SIP Configuration**, and then SIP page 1 of 2.

2 In the **Default domain** field, type in the IP address of the KWS300 server.

Figure 4-5 SIP Configuration Page

Subscribing DECT handsets

To Subscribe Handsets

1 Get the ARI Code from the DECT system from the administration page. Click **Status**, and then **Wireless server**. Note down the code, as you will need it later. In the following example, the ARI code is 000046550005

Figure 4-6 ARI Code Example

2 Click **Configuration**, and then **Wireless server**. Check **Subscription allowed** and **Autocreate Users**.

Figure 4-7 Wireless Server Configuration

You can now subscribe the handsets.

Subscribing 40XX

The following is a list of Key button functions

- "MENU" - Go to menu structure or exit the menu structure.
- " < ", "REDIAL" - Menu: left, Cursor left
- " > ", "BOOK" - Menu: right, Cursor right
- "√", "MUTE" - Confirmation ("YES") or jump to next level in the menu.

To create a subscription

.On the handset, press the following sequence.

Menu < < √ < < √

1. Press menu
2. Press left arrow twice
3. Press enter
4. Press left arrow twice
5. Press enter
6. Verify that the handset displays the following message: "SUBSCRIPTION SEARCH ID".
7. If there's more than one DECT systems in range, a list of all DECT ARI codes is created. Select the correct ARI for your system (scroll with the arrow keys), and then press the "√" key.
   For more information about the handset, download the user guide from the Polycom web site:
   http://www.polycom.com/common/documents/support/setup_maintenance/products/voice/Kirk_4020_4040_English.pdf
8. To complete the subscription, go to the KWS300 web administration page. Click **Users**, and then **List Users**.

Figure 4-8 Users administration page

The handset you just subscribed is listed with the corresponding 12 digit IPEI number.

9. Click a number in the User column, to access the individual handset administration page, and then enter the following information.

   DECT part information:

   - IPEI – Already filled in by KWS300. If you type this manually, it is the unique IPEI number of the handset.
   - Access code – OPTIONAL. A 4 digit code, which you choose (e.g. 1111). May be left blank. Use this field if you want to increase the security for the system. The handset must be subscribed again if you change this setting.
   - •Standby text – OPTIONAL. Use the User name/extension number here, so you can easily identify the handset number.

SIP Part information (These parameters must be similar to corresponding settings for the account at the IP PBX):

- Username/Extension. Use the Extension number you want (for example, 100 for the first handset, 101 for the next handset, etc.)
- Domain. Leave this blank.
- Displayname. Display name used in the IP PBX. Use the extension number to easily identify the handset number.
- Authentication user. Leave this blank.
- Authentication password. Leave this blank.

Other settings

- Disabled checkbox.When checked, the handset is inactive (can not receive and/or transmit calls). Uncheck to activate the handset.
- MSF Local Number. Leave this blank.
